

Diet and age effects on systolic left ventricular internal diameter (mm)

Only the following timepoints were used when testing for direct diet and age-diet interaction effects (all timepoints were used when testing for direct age effects): 10 months and 22 months. The effects of age, diet, and the age-diet interaction were estimated using mixed linear models and the significance of the effects were assessed with an approximate F-test using the Kenward and Roger (1997) approach. The p-values for the diet effect at each timepoint are: 10 months = 3.99×10^{-5} and 22 months = 0.177. The diet pairs that have significantly different (Tukey p-value < 0.05) means at 10 months are 1D-40, 2D-20 and 20-40. The p-value for the direct effect of age on LVID_sys is 0.454. The p-value for the effect of the interaction between age and diet on LVID_sys is 0.00397. The diet pairs that have significantly different (Tukey p-value < 0.05) rates of change with age are 2D-20 and 20-40.
