

# Diet and age effects on % of viable cells that are monocytes

Only the following timepoints were used when testing for direct diet and age-diet interaction effects (all timepoints were used when testing for direct age effects): 05 months, 16 months and 28 months. The effects of age, diet, and the age-diet interaction were estimated using mixed linear models and the significance of the effects were assessed with an approximate F-test using the Kenward and Roger (1997) approach. The p-values for the diet effect at each timepoint are: 05 months = 0.00613; 16 months = 4.48e-08 and 28 months = 0.00316. The diet pairs that have significantly different (Tukey p-value < 0.05) means at 05 months are AL-2D. The diet pairs that have significantly different (Tukey p-value < 0.05) means at 16 months are AL-2D, AL-20, AL-40 and 1D-2D. The diet pairs that have significantly different (Tukey p-value < 0.05) means at 28 months are AL-40, 1D-40 and 2D-40. The p-value for the direct effect of age on Mono\_PercViable is 2.48e-07. The p-value for the effect of the interaction between age and diet on Mono\_PercViable is 1.09e-05. The diet pairs that have significantly different (Tukey p-value < 0.05) rates of change with age are AL-40, 1D-40 and 2D-40.
