

Diet and age effects on neutrophil count ($10^3/\mu\text{L}$)

Only the following timepoints were used when testing for diet and age effects: 11 months and 23 months. The effects were estimated using mixed linear models and the significance of the effects were assessed with an approximate F-test using the Kenward and Roger (1997) approach. The p-values for the diet effect at each timepoint are: 11 months = 0.0486 and 23 months = 0.0114. The diet pairs that have significantly different (Tukey p-value < 0.05) means at 11 months are 2D-20. The diet pairs that have significantly different (Tukey p-value < 0.05) means at 23 months are 1D-40 and 2D-20. The p-value for the direct effect of age on NumNeut is 5.24×10^{-7} . The p-value for the effect of the interaction between age and diet on NumNeut is 3.48×10^{-5} . The diet pairs that have significantly different (Tukey p-value < 0.05) rates of change with age are 1D-20, 1D-40, 2D-20 and 2D-40.
