

Diet and age effects on % of double negative T cells that are CD62L– and CD44–

Only the following timepoints were used when testing for diet and age effects: 05 months, 16 months and 28 months. The effects were estimated using mixed linear models and the significance of the effects were assessed with an approximate F-test using the Kenward and Roger (1997) approach. The p-values for the diet effect at each timepoint are: 05 months = 0.365; 16 months = 1.39e-07 and 28 months = 1.01e-05. The diet pairs that have significantly different (Tukey p-value < 0.05) means at 16 months are AL-2D, 1D-40 and 2D-40. The diet pairs that have significantly different (Tukey p-value < 0.05) means at 28 months are AL-40, 1D-40, 2D-40 and 20-40. The p-value for the direct effect of age on DNT_CD62LnegCD44negPercDNT is 3.42e-09. The p-value for the effect of the interaction between age and diet on DNT_CD62LnegCD44negPercDNT is 2.67e-12. The diet pairs that have significantly different (Tukey p-value < 0.05) rates of change with age are AL-40, 1D-40, 2D-40 and 20-40.
