

# Diet and age effects on Vaginal or uterine prolapse (0, 0.5, 1)

Only the following timepoints were used when testing for direct diet and age–diet interaction effects (all timepoints were used when testing for direct age effects): 05 months, 08 months, 10 months, 16 months, 22 months and 28 months. The effects of age, diet, and the age–diet interaction were estimated using mixed linear models and the significance of the effects were assessed with an approximate F–test using the Kenward and Roger (1997) approach. The p–values for the diet effect at each timepoint are: 05 months = NA; 08 months = NA; 10 months = NA; 16 months = NA; 22 months = NA and 28 months = 0.491. The p–value for the direct effect of age on Vaginal/Uterine Prolapse is 0.212. The p–value for the effect of the interaction between age and diet on Vaginal/Uterine Prolapse is 0.0149. The diet pairs that have significantly different (Tukey p–value < 0.05) rates of change with age are AL–1D, 1D–2D, 1D–20 and 1D–40.
