

# Diet and age effects on cardiac output (micro liters per minute): BPM \* StrokeVolume

Only the following timepoints were used when testing for direct diet and age-diet interaction effects (all timepoints were used when testing for direct age effects): 10 months and 22 months. The effects of age, diet, and the age-diet interaction were estimated using mixed linear models and the significance of the effects were assessed with an approximate F-test using the Kenward and Roger (1997) approach. The p-values for the diet effect at each timepoint are: 10 months = 0.000714 and 22 months = 0.312. The diet pairs that have significantly different (Tukey p-value < 0.05) means at 10 months are AL-2D, 2D-20 and 20-40. The p-value for the direct effect of age on CardiacOutput is 0.00262. The p-value for the effect of the interaction between age and diet on CardiacOutput is 0.0644.
