

# Diet and age effects on % of natural killer cells that are CD11B+ and CD11C+

Only the following timepoints were used when testing for direct diet and age-diet interaction effects (all timepoints were used when testing for direct age effects): 05 months, 16 months and 28 months. The effects of age, diet, and the age-diet interaction were estimated using mixed linear models and the significance of the effects were assessed with an approximate F-test using the Kenward and Roger (1997) approach. The p-values for the diet effect at each timepoint are: 05 months = 0.236; 16 months = 1.53e-05 and 28 months = 3.17e-06. The diet pairs that have significantly different (Tukey p-value < 0.05) means at 16 months are AL-40, 1D-40, 2D-40 and 20-40. The diet pairs that have significantly different (Tukey p-value < 0.05) means at 28 months are AL-40, 1D-40, 2D-40 and 20-40. The p-value for the direct effect of age on NK\_CD11BposCD11CposPercNK is 0.465. The p-value for the effect of the interaction between age and diet on NK\_CD11BposCD11CposPercNK is 3.18e-09. The diet pairs that have significantly different (Tukey p-value < 0.05) rates of change with age are AL-40, 1D-20, 1D-40, 2D-40 and 20-40.
