

Diet and age effects on percent monocytes (%) = NumMono / NumWBC

Only the following timepoints were used when testing for direct diet and age-diet interaction effects (all timepoints were used when testing for direct age effects): 11 months and 23 months. The effects of age, diet, and the age-diet interaction were estimated using mixed linear models and the significance of the effects were assessed with an approximate F-test using the Kenward and Roger (1997) approach. The p-values for the diet effect at each timepoint are: 11 months = 3.02×10^{-11} and 23 months = 0.0024. The diet pairs that have significantly different (Tukey p-value < 0.05) means at 11 months are AL-1D, AL-2D, AL-20, AL-40 and 1D-2D. The diet pairs that have significantly different (Tukey p-value < 0.05) means at 23 months are AL-1D, AL-20 and AL-40. The p-value for the direct effect of age on PercMono is 3.14×10^{-6} . The p-value for the effect of the interaction between age and diet on PercMono is 0.0448. The diet pairs that have significantly different (Tukey p-value < 0.05) rates of change with age are 1D-2D.
