

Diet and age effects on The trimmed mean of fore-paw grip strength (grams)

Only the following timepoints were used when testing for direct diet and age-diet interaction effects (all timepoints were used when testing for direct age effects): 05 months, 11 months, 17 months and 23 months. The effects of age, diet, and the age-diet interaction were estimated using mixed linear models and the significance of the effects were assessed with an approximate F-test using the Kenward and Roger (1997) approach. The p-values for the diet effect at each timepoint are: 05 months = 0.34; 11 months = 0.0262; 17 months = 0.00941 and 23 months = 0.0253. The diet pairs that have significantly different (Tukey p-value < 0.05) means at 11 months are AL-40. The diet pairs that have significantly different (Tukey p-value < 0.05) means at 17 months are AL-40. The diet pairs that have significantly different (Tukey p-value < 0.05) means at 23 months are 20-40. The p-value for the direct effect of age on Fore is $1.62e-06$. The p-value for the effect of the interaction between age and diet on Fore is 0.846.
