

Diet and age effects on % of of viable cells that are NKG2D+ T cells

Only the following timepoints were used when testing for direct diet and age–diet interaction effects (all timepoints were used when testing for direct age effects): 05 months, 16 months and 28 months. The effects of age, diet, and the age–diet interaction were estimated using mixed linear models and the significance of the effects were assessed with an approximate F–test using the Kenward and Roger (1997) approach. The p–values for the diet effect at each timepoint are: 05 months = 0.937; 16 months = 0.00143 and 28 months = 0.969. The diet pairs that have significantly different (Tukey p–value < 0.05) means at 16 months are 1D–40 and 2D–40. The p–value for the direct effect of age on NKG2DposT_PercViable is 9.86×10^{-5} . The p–value for the effect of the interaction between age and diet on NKG2DposT_PercViable is 0.669.
